Conformal transformations play a widespread role in gravity theories in regard to their cosmological and other implications. In the pure metric theory of gravity, conformal transformations change the frame to a new one wherein one obtains a conformal-invariant scalar-tensor theory such that the scalar field, deriving from the conformal factor, is a ghost.

In this work, conformal transformations and ghosts will be analyzed in the framework of the metric-affine theory of gravity. Within this framework, metric and connection are independent variables, and hence, transform independently under conformal transformations. It will be shown that, if affine connection is invariant under conformal transformations then the scalar field under concern is a non-ghost, non-dynamical field. It is an auxiliary field at the classical level, and might develop a kinetic term at the quantum level.

Alternatively, if connection transforms additively with a structure similar to yet more general than that of the Levi-Civita connection, the resulting action describes the gravitational dynamics correctly, and more importantly, the scalar field becomes a dynamical non-ghost field. The equations of motion, for generic geometrical and matter-sector variables, do not reduce connection to the Levi-Civita connection, and hence, independence of connection from metric is maintained. Therefore, metric-affine gravity provides an arena in which ghosts arising from conformal factor are avoided thanks to the independence of connection from the metric.

INTRODUCTION

Spacetime is a smooth manifold $\mathcal{M}(g, \Gamma)$ endowed with a metric g and connection Γ . Metric is responsible for measuring the distances while connection governs curving and twirling of the manifold. Connection specifies how vectors and tensors are to be differentiated in curved spacetime. We hereby emphasize that only the symmetric connections *i.e.* torsion-free spacetimes will be considered throughout in this work. These two geometrical structures, the metric and connection, are fundamentally independent geometrical variables, and they play completely different roles in spacetime dynamics. If they are to exhibit any relationship it derives from dynamical equations *a posteriori*. This fact, that the metric and connection are independent geometrical variables, gives rise to two alternative approaches to General Relativity (GR):

1. GR with metricity only ,
2. GR with affinity and metricity .

The former is a purely metric theory of gravity since connection is completely determined by the metric and its partial derivatives, *a priori*. This determination is encoded in the Levi-Civita connection, $\tilde{\Gamma}$ as

$$\tilde{\Gamma}_{\alpha\beta}^{\lambda} = \frac{1}{2}g^{\lambda\rho} (\partial_{\alpha}g_{\beta\rho} + \partial_{\beta}g_{\rho\alpha} - \partial_{\rho}g_{\alpha\beta}) , \quad (1)$$

which defines a metric-compatible covariant derivative [1]. In this particular setup, the Einstein-Hilbert action produces gravitational field equations only by adding an extrinsic curvature term.

The metric-affine gravity (similar to the Palatini formalism[2–4] in philosophy), which considers an independence of metric tensor and connection [1, 5], encodes a more general approach to gravitation by breaking up the *a priori* relation (1). In this approach, gravitational field equations are successfully produced with no need to extrinsic curvature term provided that the geometrical sector is minimal and matter sector is independent of the connection [5]. Concerning the matter sector, the fermion kinetic term [6] and coupling between scalar fields and curvature scalar [7] are just two examples that immediately come to mind.

This work is about yet another difference between the metrical and affine approaches to gravity. Conformal transformation is essentially a local change of scale. Since distances are measured by metric, such transformations executed by rescaling the metric by a smooth, nonvanishing and space-time dependent function $\Omega(x)$, called the conformal factor [1, 8]. Therefore, the transformation

$$\tilde{g}_{\alpha\beta} = \Omega^2(x) g_{\alpha\beta} \quad (2)$$

which shrinks or stretches the distances on the manifold locally.

Conformal transformations are particularly respectful to distinction between metric and connection. Indeed, transformation of the metric in (2) automatically induces a transformation of the Levi-Civita connection as

$$\tilde{\Gamma}_{\alpha\beta}^{\lambda} = \check{\Gamma}_{\alpha\beta}^{\lambda} + \Delta_{\alpha\beta}^{\lambda} \quad (3)$$

with

$$\Delta_{\alpha\beta}^{\lambda} = \delta_{\beta}^{\lambda} \partial_{\alpha} \ln \Omega + \delta_{\alpha}^{\lambda} \partial_{\beta} \ln \Omega - g_{\alpha\beta} \partial^{\lambda} \ln \Omega. \quad (4)$$

However, this direct correlation is completely lost in the metric-affine gravity since there is no telling of how the general connection

$$\Gamma_{\alpha\beta}^{\lambda} \neq \check{\Gamma}_{\alpha\beta}^{\lambda}(g) \quad (5)$$

should transform under a rescaling of distances. In fact, the fact that connection has nothing to do with measuring the distances can be taken to imply that the connection $\Gamma_{\alpha\beta}^{\lambda}$ is completely inert under (2). However, it is still possible that connection still transforms in some way, not necessarily like (3). Stating in a clearer fashion, there arise two main categories to be explored:

- The connection Γ can be conformal-invariant: $\Gamma_{\alpha\beta}^{\lambda} \rightarrow \Gamma_{\alpha\beta}^{\lambda}$ despite (2) [8],
- The connection Γ can transform in various ways: Multiplicatively, additively or both while metric transforms as in (2).

Each of these two possibilities gives rise to novel effects not found in metrical GR, as indicated by the dependence of the Riemann curvature tensor on the connection

$$\mathbb{R}_{\mu\beta\nu}^{\alpha}(\Gamma) = \partial_{\beta} \Gamma_{\mu\nu}^{\alpha} - \partial_{\nu} \Gamma_{\mu\beta}^{\alpha} + \Gamma_{\beta\lambda}^{\alpha} \Gamma_{\mu\nu}^{\lambda} - \Gamma_{\nu\lambda}^{\alpha} \Gamma_{\mu\beta}^{\lambda}. \quad (6)$$

It is obvious that the two conformal transformation categories mentioned above will, in general, lead to completely new dynamics with no analogue in metrical GR. This work is devoted to a comparative analysis of conformal transformations in the GR with metricity and GR with affinity in the pathways described by these two categories.

In the body of the work below, we first give a discussion of metrical GR. Following this we turn to a detailed analysis of the metric-affine gravity by exploring plausible alternatives one by one. After this, in the last section, we discuss certain salient features of the model not covered in the text and conclude.

CONFORMAL TRANSFORMATIONS IN GR WITH METRICITY

In metrical GR, conformal transformation of the metric (2) automatically leads to transformation of the connection (3), and hence, of the Riemann curvature tensor (6). The transformed Riemann tensor reads as

$$\begin{aligned} \tilde{R}_{\mu\beta\nu}^{\alpha}(\tilde{\Gamma}) &= R_{\mu\beta\nu}^{\alpha}(\check{\Gamma}) + [\delta_{\beta}^{\alpha} \delta_{\nu}^{\lambda} \delta_{\mu}^{\rho} - \delta_{\nu}^{\alpha} \delta_{\beta}^{\lambda} \delta_{\mu}^{\rho} + \delta_{\beta}^{\lambda} g_{\mu\nu} g^{\alpha\rho} \\ &\quad - \delta_{\nu}^{\lambda} g_{\mu\beta} g^{\alpha\rho}] (2\partial_{\lambda} \ln \Omega \partial_{\rho} \ln \Omega - \nabla_{\lambda} \partial_{\rho} \ln \Omega) \\ &\quad + [\delta_{\nu}^{\alpha} g_{\mu\beta} g^{\lambda\rho} - \delta_{\beta}^{\alpha} g_{\mu\nu} g^{\lambda\rho}] \partial_{\lambda} \ln \Omega \partial_{\rho} \ln \Omega \end{aligned} \quad (7)$$

where use has been made of the definition $\mathbb{R}_{\mu\beta\nu}^{\alpha}(\Gamma = \check{\Gamma}) \equiv R_{\mu\beta\nu}^{\alpha}(\check{\Gamma})$. Contraction of this rank (1,3) tensor gives the transformed Ricci tensor

$$\begin{aligned} \tilde{R}_{\mu\nu}(\tilde{\Gamma}) &= R_{\mu\nu}(\check{\Gamma}) - [(D-2)\nabla_{\mu} \nabla_{\nu} + g_{\mu\nu} \square] \ln \Omega \\ &\quad + [2(D-2)\delta_{\mu}^{\alpha} \delta_{\nu}^{\beta} - (D-3)g_{\mu\nu} g^{\alpha\beta}] \partial_{\alpha} \ln \Omega \partial_{\beta} \ln \Omega \end{aligned} \quad (8)$$

so that transformed Ricci scalar takes the form

$$\begin{aligned} \tilde{R}(\tilde{\Gamma}) &= \tilde{g}^{\mu\nu} \tilde{R}_{\mu\nu}(\tilde{\Gamma}) \\ &= \Omega^{-2} [R(\check{\Gamma}) - 2(D-1)\square \ln \Omega - (D-1)(D-2)g^{\alpha\beta} \partial_{\alpha} \ln \Omega \partial_{\beta} \ln \Omega]. \end{aligned} \quad (9)$$

These transformation properties dictate how gravitational action density transforms under conformal rescalings. The Einstein-Hilbert action reads in $(g, \tilde{\Gamma})$ frame as

$$S_{EH} [g] = \int d^D x \sqrt{-g} \left[\frac{1}{2} M_\star^{D-2} R - \Lambda_\star + \mathcal{L}_m (g, \Psi) \right] \quad (10)$$

where M_\star is the fundamental scale of gravity in D dimensions, Λ_\star is the cosmological term, and \mathcal{L}_m is the Lagrangian of the matter and radiation fields, collectively denoted by Ψ . For the metric $(-, +, \dots, +)$ convention is adopted. Under the conformal transformation of the metric (2), this action becomes in $(\tilde{g}, \tilde{\Gamma})$ frame

$$\begin{aligned} S_{EH} [g, \bar{\phi}] &= \int d^D x \sqrt{-g} \left\{ \frac{1}{2} M_\star^{D-2} [\Omega^{D-2} R - 2(D-1)\Omega^{D-2} \square \ln \Omega \right. \\ &\quad \left. - (D-1)(D-2)\Omega^{D-4} g^{\alpha\beta} \nabla_\alpha \Omega \nabla_\beta \Omega] - \Lambda_\star \Omega^D + \tilde{\mathcal{L}}_m (g, \tilde{\Psi}) \right\} \\ &\equiv \int d^D x \sqrt{g} \left[\frac{1}{2} g^{\mu\nu} (\partial_\mu \bar{\phi}) (\partial_\nu \bar{\phi}) + \frac{1}{2} \zeta_D \bar{\phi}^2 R - \lambda_D (\zeta_D \bar{\phi}^2)^{\frac{D}{D-2}} + \tilde{\mathcal{L}}_m (g, \tilde{\Psi}) \right] \end{aligned} \quad (11)$$

where the two dimensionless constants

$$\zeta_D = \frac{D-2}{4(D-1)}, \quad \lambda_D = \frac{\Lambda_\star}{M_\star^D} \quad (12)$$

designate, respectively, the conformal coupling of $\bar{\phi}$ to R and the self-coupling of $\bar{\phi}$. The scalar field $\bar{\phi}$

$$\bar{\phi} = \frac{1}{\sqrt{\zeta_D}} (M_\star \Omega)^{\frac{(D-2)}{2}} \quad (13)$$

derives from the conformal factor Ω in order to have canonical kinetic term. The quantity $\tilde{\mathcal{L}}_m (g, \tilde{\Psi})$ in (11) is the transformed matter Lagrangian, where each matter field Ψ transforms, together with the metric, by an appropriate conformal weight. The conformal weights of fields (charges of fields under scalings) are determined from (global) conformal invariance of their kinetic terms [9, 10].

There are certain salient features of the transformed action (11), which deserve a detailed discussion.

- First of all, this action executes local conformal invariance (the Weyl invariance) under the transformations

$$g_{\alpha\beta} \longrightarrow \psi^2 g_{\alpha\beta}, \quad \bar{\phi} \longrightarrow \psi^{-\frac{(D-2)}{2}} \bar{\phi} \quad (14)$$

where inhomogeneous terms generated by the kinetic term of $\bar{\phi}$ are neutralized by the terms generated by the transformation of the curvature scalar R . This happens thanks to the special, conformal value of ζ_D . Therefore, the transformed action (11) provides a locally conformal-invariant representation of the original Einstein-Hilbert action (10). Notably, the original action (10) exhibits no sign of conformal invariance but the transformed one does and the reason behind it is the dressing of M_\star and Λ_\star by the transformation field Ω [11, 12].

- One can also notice that; conformal transformation, like Gauge transformations, adds a new degree of freedom to the system. This is a built-in property of the system; this is common to 'transformations' including the gauge transformations.
- Another point to notice about (11) is that the scalar field $\bar{\phi}$ (which is a function of the conformal factor Ω) is a ghost [13–15]. This is an unavoidable feature if gravity is to be an attractive force. Its ghostly nature follows from its non-positive kinetic term, and it signals that the system has no lower bound for energy. Such systems are inherently unphysical, and there seems to be no way of avoiding it unless some nonlinearities are added as extra features [16–18].
- The transformed action (11), when $\tilde{g}_{\alpha\beta} = \eta_{\alpha\beta}$, leads to a $\bar{\phi}^4$ theory in $D = 4$ dimensions. In this particular case spacetime is flat, and entire gravitational effects reduce to a conformal-invariant scalar field theory. This theory has been argued to exhibit an infrared fixed point at $\lambda_D = 0$, and this feature has been suggested to provide a solution to the cosmological constant problem (λ_D is proportional to the vacuum energy density Λ_\star in D dimensions) [20].

CONFORMAL TRANSFORMATIONS IN GR WITH AFFINITY

As mentioned in Introduction, GR with affinity treats metric and connection as independent geometric variables, as they indeed are. One of the most important consequences of this feature is that, conformal transformation of metric tensor gives rise to no direct change in connection, as happens in GR with metricity. Therefore, parallel to the classification made in Introduction, in this section we shall analyze conformal transformations in two separate cases in regard to the transformation properties of the connection. In course of the analysis, the main goal will be to find appropriate transformation rules for $\Gamma_{\alpha\beta}^{\lambda}$ so that the resulting scalar field theory (in terms of the conformal factor Ω) assumes physically sensible properties like emergent conformal invariance and absence of ghosts. Indeed, the main problem with the metrical GR discussed above is the unavoidable presence of a ghostly scalar in the spectrum. We will find that affine GR is capable of realizing conformal invariance and accommodating non-ghost scalar degrees of freedom.

In the metric-affine gravity, the Einstein-Hilbert action can be written as

$$S_{EH} [g, \Gamma] = \int d^D x \sqrt{-g} \left\{ \frac{1}{2} M_{\star}^{D-2} g^{\mu\nu} \mathbb{R}_{\mu\nu} (\Gamma) - \Lambda_{\star} + \mathcal{L} (\Gamma - \check{\Gamma}, g, \Psi) \right\} \quad (15)$$

in a general (g, Γ) frame. In here, Ψ collectively denotes the matter fields, and \mathcal{L} is composed of

$$\mathcal{L} = \mathcal{L}_{\text{geo}} (g, \mathcal{D}) + \mathfrak{L}_m (g, \mathcal{D}, \Psi) \quad (16)$$

which, respectively, stand for the geometrical and matter sector contributions. The geometrical sector consists of the rank (1,2) tensor field

$$\mathcal{D}_{\alpha\beta}^{\lambda} = \Gamma_{\alpha\beta}^{\lambda} - \check{\Gamma}_{\alpha\beta}^{\lambda} \quad (17)$$

as an additional geometrodynamical tensorial quantity. This variable is highly natural to consider since in the presence of the metric $g_{\alpha\beta}$ one naturally defines its compatible connection *i. e.* the Levi-Civita connection. Then difference between $\Gamma_{\alpha\beta}^{\lambda}$ and Levi-Civita connection becomes a tensorial quantity to be taken into account.

Here it is useful to clarify the meaning of $\mathcal{L}_{\text{geo}} (g, \mathcal{D})$ in terms of the known dynamical quantities akin to non-Riemannian geometries. Non-Riemannian geometries are characterized by torsion tensor $\mathbb{S}_{\alpha\beta}^{\lambda} = \mathcal{D}_{\alpha\beta}^{\lambda} - \mathcal{D}_{\beta\alpha}^{\lambda}$, non-metricity $\mathbb{Q}_{\lambda}^{\alpha\beta} = \mathcal{D}_{\lambda\rho}^{\alpha} g^{\rho\beta} + \mathcal{D}_{\lambda\rho}^{\beta} g^{\alpha\rho}$, the Ricci curvature tensor $\mathbb{R}_{\mu\nu} (\Gamma) = \mathbb{R}_{\mu\alpha\nu}^{\alpha} (\Gamma)$, and the other Ricci curvature tensor $\mathbb{R}'_{\beta\nu} = \mathbb{R}_{\alpha\beta\nu}^{\alpha} (\Gamma)$. All these tensor fields make up the geometrical sector of the theory which obviously span a much larger set compared to the purely metric formulation (GR). In GR connection and metric are put in direct relation from the scratch. However, physically, it is more natural to induce a relation between them, if any, as a result of dynamical equations [21]. This is what is done by the Palatini formalism where metricity appears in the system automatically via the equations of motion. In metric-affine gravity we explore here metric and connection continue to be independent geometrical variables with no harm from their equations of motion (See Appendix A for further details.). One crucial aspect of non-Riemannian geometries (with non-vanishing torsion and/or nonmetricity) is to provide a compact structuring of various tensor fields which can play important roles in cosmology [22].

Clearly, torsion vanishes for theories with symmetric connections, and this is also the case throughout the present work. Although the torsion-free cases are studied for simplicity, the nonmetricity, which relaxes the restrictions on the theory, still holds. Moreover, $\mathbb{R}'_{\beta\nu}$ is an anti-symmetric tensor field whose curvature scalar vanishes identically. This tensor can give contributions to Lagrangian at the quadratic and higher levels. The Lagrangian $\mathcal{L}_{\text{geo}} (g, \mathcal{D})$ includes all these tensorial contributions through the $\mathcal{D}_{\alpha\beta}^{\lambda}$ dependence

$$\mathcal{L}_{\text{geo}} (g, \mathcal{D}) = \mathcal{L}_{\text{geo}} (g, \mathbb{S}, \mathbb{Q}, \mathbb{R}, \mathbb{R}') , \quad (18)$$

throughout the text. It is clear that, \mathcal{L}_{geo} can involve arbitrary powers and derivatives of the tensorial connection $\mathcal{D}_{\alpha\beta}^{\lambda}$.

It is clear that the Lagrangian \mathcal{L} , through its Γ or \mathcal{D} dependence, gives rise to important modifications in the equations of motion [23] so that $\Gamma = \check{\Gamma}$ limit (which is precisely what is behind the Palatini formulation) does not necessarily hold. The contributions of $\mathcal{L}_{\text{geo}} (g, \mathcal{D})$ and $\mathfrak{L}_m (g, \mathcal{D}, \Psi)$ generically avoid the limit $\Gamma = \check{\Gamma}$. We will discuss this point below. In the following section, however, we will focus on the transformation properties of (15) without considering the contributions of $\mathcal{L}_{\text{geo}} (g, \mathcal{D})$ or $\mathfrak{L}_m (g, \mathcal{D}, \Psi)$. This is done for the purpose of definiteness and simplicity. Nevertheless, in Appendix A, we shall come back to the effects of \mathcal{L} , especially the $\mathcal{L}_{\text{geo}} (g, \mathcal{D})$, and give a detailed discussion of the equations of motion and other features.

Conformal-Invariant Connection

We start the analysis by first considering a conformal-invariant connection by which we mean that connection is inert to rescalings of the metric. Therefore, along with the transformation of metric (2), the connection transforms as [8]

$$\tilde{\Gamma}_{\alpha\beta}^{\lambda} = \Gamma_{\alpha\beta}^{\lambda} \quad (19)$$

and hence,

$$\tilde{\mathbb{R}}_{\mu\beta\nu}^{\alpha}(\tilde{\Gamma}) = \mathbb{R}_{\mu\beta\nu}^{\alpha}(\Gamma), \quad \tilde{\mathbb{R}}_{\mu\nu}(\tilde{\Gamma}) = \mathbb{R}_{\mu\nu}(\Gamma) \quad (20)$$

since Riemann tensor (6) does not involve the metric tensor unless the connection does. The only non-trivial transformation occurs for the Ricci scalar

$$\tilde{g}^{\mu\nu}\tilde{\mathbb{R}}_{\mu\nu}(\tilde{\Gamma}) = \Omega^{-2}g^{\mu\nu}\mathbb{R}_{\mu\nu}(\Gamma) \quad (21)$$

which is nothing but an overall dressing by Ω^{-2} . In particular, no derivatives of Ω are involved in the transformations of curvature tensors. This implies that Ω can develop no kinetic term. Indeed, under the transformation (21), the action (15) with conformal-invariant connection goes over

$$S_{EH}[\tilde{g}, \tilde{\Gamma}, \tilde{\phi}] = \int d^D x \sqrt{-g} \left[\frac{1}{2} \zeta_D \tilde{\phi}^2 g^{\mu\nu} \mathbb{R}_{\mu\nu}(\Gamma) - \lambda_D \left(\zeta_D \tilde{\phi}^2 \right)^{\frac{D}{D-2}} \right] \quad (22)$$

in $(\tilde{g}, \tilde{\Gamma})$ frame and in the absence of the geometrical and matter parts \mathcal{L} . Obviously, this action is locally conformal invariant under

$$g_{\alpha\beta} \longrightarrow \psi^2 g_{\alpha\beta}, \quad \Gamma_{\alpha\beta}^{\lambda} \longrightarrow \Gamma_{\alpha\beta}^{\lambda}, \quad \tilde{\phi} \longrightarrow \psi^{-\frac{(D-2)}{2}} \tilde{\phi} \quad (23)$$

as was the case for metrical gravity, defined in (14). Therefore, though the original action (15) exhibits no sign of conformal invariance and hence the new action (22) arises, this transformed action exhibits manifest conformal invariance. The reason is as in the metrical gravity; the conformal factor Ω dresses the fixed scales (M_* and Λ_*) in (15) to make them as effective fields transforming nontrivially under local rescalings of the fields [11].

Apart from this emergent conformal invariance, the action (22) possesses a highly important aspect not found in metrical GR: It is that $\tilde{\phi}$ is not a ghost at all. It is a non-dynamical scalar field having vanishing kinetic energy, and thus, the impasse caused by the ghostly scalar field encountered in metrical GR is resolved. The non-dynamical nature of $\tilde{\phi}$ continues to hold even if the matter sector is included. This result stems from the affine nature of the gravitational theory under concern, and especially from the invariance of the connection under conformal transformations.

At this point it proves useful to discuss the ‘non-dynamical’ nature of the scalar field $\tilde{\phi}$ in the action (22). At the level of the transformations employed and the Einstein-Hilbert action the non-dynamical nature of the conformal factor (and hence, the $\tilde{\phi}$) is unavoidable. However, one immediately notices that this ‘non-dynamical’ structure depends sensitively on the quantum fluctuations. Indeed, if quantum fluctuations are included into (22) the scalar field $\tilde{\phi}$ is found to develop a kinetic term via the graviton loops [24]. We shall keep analysis at the classical level throughout the work. However, one is warned of such delicate effects which can come from quantum corrections or higher order geometrical invariants.

Conformal-Variant Connection

As an alternative to conformal-invariant connection, in this subsection we investigate different scenarios where $\Gamma_{\alpha\beta}^{\lambda}$ exhibits nontrivial changes along with the transformation of the metric in (2).

As a possible transformation property, we first discuss the multiplicative transformation of connection. Namely, connection transforms similar to the metric itself

$$\tilde{\Gamma}_{\alpha\beta}^{\lambda} = f(\Omega) \Gamma_{\alpha\beta}^{\lambda} \quad (24)$$

where $f(\Omega)$ is a generic function of the conformal factor. Inserting this transformed connection into (6), one straightforwardly determines the transformed Riemann tensor

$$\begin{aligned} \tilde{\mathbb{R}}_{\mu\beta\nu}^{\alpha}(\tilde{\Gamma}) &= f(\Omega) \mathbb{R}_{\mu\beta\nu}^{\alpha}(\Gamma) + \partial_{\beta} f(\Omega) \Gamma_{\mu\nu}^{\alpha} - \partial_{\nu} f(\Omega) \Gamma_{\mu\beta}^{\alpha} \\ &\quad + f(\Omega) (f(\Omega) - 1) [\Gamma_{\beta\lambda}^{\alpha} \Gamma_{\mu\nu}^{\lambda} - \Gamma_{\nu\lambda}^{\alpha} \Gamma_{\mu\beta}^{\lambda}] \end{aligned} \quad (25)$$

and hence the transformed Ricci scalar

$$\begin{aligned} \tilde{g}^{\mu\nu} \tilde{\mathbb{R}}_{\mu\nu}(\tilde{\Gamma}) &= \Omega^{-2} \left\{ f(\Omega) \mathbb{R}(\Gamma) + \partial_\alpha f(\Omega) g^{\mu\nu} \Gamma_{\mu\nu}^\alpha - \partial_\nu f(\Omega) g^{\mu\nu} \Gamma_{\mu\alpha}^\alpha \right. \\ &\quad \left. + f(\Omega) (f(\Omega) - 1) [\Gamma_{\alpha\lambda}^\alpha g^{\mu\nu} \Gamma_{\mu\nu}^\lambda - \Gamma_{\nu\lambda}^\alpha g^{\mu\nu} \Gamma_{\mu\alpha}^\lambda] \right\}. \end{aligned} \quad (26)$$

It is straightforward to check that the Γ -dependent terms at the right-hand side form a true scalar under general coordinate transformations (See Appendix B for details). This conformal transformation rule for Ricci scalar dictates what form the gravitational action (15) in (g, Γ) frame takes in $(\tilde{g}, \tilde{\Gamma})$ frame. It is clear that the transformed action will involve Ω as well as its partial derivatives. Therefore, contrary to the previous case of conformal-invariant connection, Ω is a dynamical field. However, it does not possess a true kinetic term in the sense of a scalar field theory. Its derivative interactions are always accompanied by the connection, $\Gamma_{\alpha\beta}^\lambda$.

As another transformation property of the connection, we now turn to analysis of additive transformation of $\Gamma_{\alpha\beta}^\lambda$. We thus consider the generic transformation rule

$$\tilde{\Gamma}_{\alpha\beta}^\lambda = \Gamma_{\alpha\beta}^\lambda + \Delta_{\alpha\beta}^\lambda(\Omega) \quad (27)$$

where $\Delta_{\alpha\beta}^\lambda(\Omega)$, being the difference between $\tilde{\Gamma}_{\alpha\beta}^\lambda$ and $\Gamma_{\alpha\beta}^\lambda$, is a rank (1,2) tensor field. It is a tensorial connection. This transformation of the connection is understood to run simultaneously with the transformation of the metric in (2). (One notes that $\Delta_{\alpha\beta}^\lambda$ here may be interpreted contain a set of vector fields like the conformal factor itself is a scalar field. See, [22] for details of such a reduction.) Then, as follows from (6), the Riemann tensor transforms as

$$\tilde{\mathbb{R}}_{\mu\beta\nu}^\alpha(\tilde{\Gamma}) = \mathbb{R}_{\mu\beta\nu}^\alpha(\Gamma) + \nabla_\beta \Delta_{\mu\nu}^\alpha - \nabla_\nu \Delta_{\mu\beta}^\alpha + \Delta_{\lambda\beta}^\alpha \Delta_{\mu\nu}^\lambda - \Delta_{\lambda\nu}^\alpha \Delta_{\beta\mu}^\lambda \quad (28)$$

where the Δ -dependent part at the right-hand side, though seems so, is not a true curvature tensor; it is not generated by any of the covariant derivatives induced by $\Gamma_{\alpha\beta}^\lambda$ or $\tilde{\Gamma}_{\alpha\beta}^\lambda$. This extra Δ -dependent piece is just a rank (1,3) tensor field induced by $\Delta_{\alpha\beta}^\lambda$ alone.

In accordance with the transformation of Riemann tensor in (28), the Ricci scalar transforms as

$$\tilde{g}^{\mu\nu} \tilde{\mathbb{R}}_{\mu\nu}(\tilde{\Gamma}) = \Omega^{-2} g^{\mu\nu} \{ \mathbb{R}_{\mu\nu}(\Gamma) + \nabla_\alpha \Delta_{\mu\nu}^\alpha - \nabla_\nu \Delta_{\mu\alpha}^\alpha + \Delta_{\lambda\alpha}^\alpha \Delta_{\mu\nu}^\lambda - \Delta_{\lambda\nu}^\alpha \Delta_{\alpha\mu}^\lambda \}. \quad (29)$$

This transformation rule is rather generic for connections which transform additively [13]. Nevertheless, it is necessary to determine physically admissible forms of $\Delta_{\alpha\beta}^\lambda$ so that the conformal factor Ω assumes appropriate dynamics in regard to absence of ghosts and emerging of a new conformal invariance in the sense of (23).

At this stage, right question to ask is this: ‘How is $\Delta_{\alpha\beta}^\lambda$ related to Ω ?’ To answer this question, one has to check out a series of possibilities. Being a rank (1,2) tensor field, $\Delta_{\alpha\beta}^\lambda$ can assume a number of forms like $V^\lambda g_{\alpha\beta}$ or $\delta_\alpha^\lambda V_\beta$ or $V^\lambda T_{\alpha\beta}$, with V_α being a vector field and $T_{\alpha\beta}$ a symmetric tensor field. If the transformation of connection (27) is to coexist with that of the metric in (2), then V_α , $T_{\alpha\beta}$ or any other structure must be related to gradients of Ω so that $\Delta_{\alpha\beta}^\lambda$ vanishes when Ω is unity or, more precisely, constant. Therefore, one may identify V_α with $\partial_\alpha \Omega$, and $T_{\alpha\beta}$ with $\nabla_\alpha \partial_\beta \Omega$ or $\partial_\alpha \Omega \partial_\beta \Omega$. Consequently, $\Delta_{\alpha\beta}^\lambda$ should be composed of $\partial^\lambda \Omega g_{\alpha\beta}$, $\delta_\alpha^\lambda \partial_\beta \Omega$ or relevant higher derivatives of Ω or higher powers of $\partial_\alpha \Omega$. Hence, at the linear level, $\Delta_{\alpha\beta}^\lambda$ must be of the form

$$\Delta_{\alpha\beta}^\lambda = c_1 \left(\delta_\alpha^\lambda \partial_\beta \ln \Omega + \delta_\beta^\lambda \partial_\alpha \ln \Omega \right) + c_2 g_{\alpha\beta} \partial^\lambda \ln \Omega \quad (30)$$

where c_1 and c_2 are real constants. In here, one notices that a very similar form of this connection was also found in [25, 26] in spacetimes with non-vanishing torsion. In [26], prescription in (30) is obtained by requiring invariance of Lorentz connection under conformal transformations. That work also points out the possibility of conformal invariant gravitational action. In addition to this, by considering a similar prescription for torsion instead of connection, one can construct a conformally-invariant theory. This option is studied in detail in [27].

That both metric and connection transform according to an assumed prescription (as given in (2) and (30), respectively) may lead one to conclude that metric and connection do actually depend on each other - not independent quantities as required by the metric-affine gravity. Actually, such a dependence does not need to exist. The situation can be clarified by considering, for example, scalar and fermion fields, comparatively. Indeed, they both transform non-trivially under conformal transformations

yet they bear no relationship at all. In this sense, one concludes that their behaviors under conformal transformations do not need to impose an inter-dependence between metric and connection.

One readily notices that the tensorial structures involved in (30) are the same as the ones appearing in the transformation of the Levi-Civita connection under conformal transformations. This is seen from direct comparison of (30) with (4). The difference is the generality of (30) in terms of the constants c_1 and c_2 since $c_1 = -c_2 = 1$ in the transformation (4) of the Levi-Civita connection. Under the transformation (30), the metric-affine action (15) in (g, Γ) frame takes the form

$$\begin{aligned}
S_{EH} [\tilde{g}, \tilde{\Gamma}, \bar{\phi}] &= \int d^D x \sqrt{-g} \left\{ \frac{1}{2} \Omega^{D-2} M_\star^{D-2} g^{\mu\nu} \mathbb{R}_{\mu\nu}(\Gamma) \right. \\
&\quad \left. + \frac{1}{2} (D-1)(D-2) \kappa_D \Omega^{D-4} M_\star^{D-2} g^{\mu\nu} \partial_\mu \Omega \partial_\nu \Omega \right. \\
&\quad \left. - \Lambda_\star \Omega^D + \tilde{\mathcal{L}} \right\} \\
&= \int d^D x \sqrt{-g} \left\{ \frac{1}{2} \text{Sign}(\kappa_D) g^{\mu\nu} \partial_\mu \bar{\phi} \partial_\nu \bar{\phi} \right. \\
&\quad \left. + \frac{1}{2} \zeta'_D \bar{\phi}^2 g^{\mu\nu} \mathbb{R}_{\mu\nu}(\Gamma) - \lambda_D \left(\zeta'_D \bar{\phi}^2 \right)^{\frac{D}{D-2}} \right\}
\end{aligned} \tag{31}$$

where use has been made of the abbreviations

$$\kappa_D = \frac{(c_1 + c_2)^2 + (D-2)c_1 c_2 + (D-2)(c_1 - c_2)}{D-2} \tag{32}$$

$$\zeta'_D = \frac{\zeta_D}{|\kappa_D|} \tag{33}$$

along with the new canonical scalar field

$$\bar{\phi} = \frac{1}{\sqrt{\zeta'_D}} (M_\star \Omega)^{\frac{D-2}{2}}. \tag{34}$$

The action (31) is to be contrasted with the transformed action (11) in metrical gravity. The differences between the two are spectacular, and it could prove useful to discuss them here in detail:

- One first notes that, the action (31) is invariant under the emergent conformal transformations

$$\begin{aligned}
g_{\alpha\beta} &\longrightarrow \psi^2 g_{\alpha\beta} \\
\Gamma_{\alpha\beta}^\lambda &\longrightarrow \Gamma_{\alpha\beta}^\lambda + \Delta_{\alpha\beta}^\lambda(\psi) \\
\bar{\phi} &\longrightarrow \psi^{-\frac{(D-2)}{2}} \bar{\phi}
\end{aligned} \tag{35}$$

similar to what we have found in (14) for the metrical GR. This invariance guarantees that all the fixed scales in (15) are appropriately dressed by the conformal factor Ω [11].

- The conformal coupling ζ_D in (11) of the pure metric gravity changes to $\zeta_D/|\kappa_D|$ in the metric-affine action under concern. The presence of κ_D reflects the generality of the transformation of the connection, as noted in (30). This is a highly important result since it generalizes the very concept of ‘conformal coupling’ between scalar fields and curvature scalar by changing ζ_D to ζ'_D . This modification can have observable consequences in cosmological [7, 28, 29] as well as collider observables [14, 30] of the GR with affinity.
- In complete contrast to (11), the scalar field $\bar{\phi}$ in (31) obtains an indefinite kinetic term. The sign of the kinetic term is determined by the sign of κ_D . One here notes two physically distinct cases:
 1. If $\kappa_D > 0$ then $\bar{\phi}$ is a scalar ghost as in the metrical GR. In (11) $\kappa_D = 1$ (since $c_1 = 1$ and $c_2 = -1$ for the change of Levi-Civita connection (4) under conformal transformations), and $\bar{\phi}$ is necessarily a ghost if gravity is to stay as an attractive force.

2. If, however, $\kappa_D < 0$ then $\bar{\phi}$ becomes a true scalar field with no problems like ghostly behavior. One notices from (31) that this very regime is realized with no modification in the attractive nature of the gravitational force. Gravity is attractive and $\bar{\phi}$ is a non-ghost, true scalar field. This result follows from the generality of the transformation of $\Gamma_{\alpha\beta}^\lambda$ in (30) compared to that of the Levi-Civita connection. The real constants c_1 and c_2 gives enough freedom to make κ_D negative for having a canonical scalar field theory, and this happens for

$$c_2 > -1 + \frac{1}{2}D(1 - c_1) - \frac{1}{2}\sqrt{(D^2 - 4)c_1^2 - 2(D^2 - 4)c_1 + (D - 2)^2}$$

and

$$c_2 < -1 + \frac{1}{2}D(1 - c_1) + \frac{1}{2}\sqrt{(D^2 - 4)c_1^2 - 2(D^2 - 4)c_1 + (D - 2)^2}$$

where c_1 is restricted to lie outside the interval $\left[\frac{D+2-2\sqrt{D+2}}{(D+2)}, \frac{D+2+2\sqrt{D+2}}{(D+2)}\right]$. One can see that for any dimension $D \geq 4$ there exist wide ranges of values of c_1 for which c_2 takes on admissible negative or positive real values. In particular, if we consider one of the most likely cases in which the constants are equal but have opposite signs, we find $\kappa_D < 0$ for $c_1 = -c_2 \notin (0, 2]$ in $D > 2$ dimensions. Similar considerations pertaining to the metric-scalar-torsion system can be found in [19].

3. The fact that the metric-affine gravity offers a true scalar field $\bar{\phi}$ elevates the arguments on the cosmological constant problem in [20] to a more physical status since one then does not need to multiply the scalar field by the imaginary unit to make sense of the resulting scalar field theory. For $\kappa_D < 0$ and $\tilde{g}_{\mu\nu} = \eta_{\mu\nu}$, the affine-gravitational action (31) can realize infrared fixed point for $\bar{\phi}$ with no artificial changes in the sign of its kinetic term.
- The geometrical part of $\mathcal{L}(g, \mathcal{D}, \Psi)$, which only consist of the metric and $\mathcal{D}_{\alpha\beta}^\lambda = \Gamma_{\alpha\beta}^\lambda - \check{\Gamma}_{\alpha\beta}^\lambda$, will also transform under conformal transformation (2) with additively conformal-variant connection (27). Under the conformal transformations (35), \mathcal{D} changes as

$$\tilde{\mathcal{D}}_{\alpha\beta}^\lambda = \mathcal{D}_{\alpha\beta}^\lambda + (c_2 + 1)g_{\alpha\beta}\partial^\lambda \ln \psi + (c_1 - 1)(\delta_\alpha^\lambda \partial_\beta \ln \psi + \delta_\beta^\lambda \partial_\alpha \ln \psi)$$

as expected from transformation properties of $\Gamma_{\alpha\beta}^\lambda$ and $\check{\Gamma}_{\alpha\beta}^\lambda$. This gives geometrodynamical terms and couplings of \mathcal{D} with the emergent scalar field ψ .

- An important problem concerns the gravitational kinetic term. In metric formulation, conformally-invariant kinetic term is provided by the Weyl tensor [13, 37]. In the present case, however, such a conformal-invariant kinetic term might be difficult to induce. Actually, what is necessary is to construct a gravitational kinetic term which is invariant under the conformal transformations in (2) and (27) (with the specific form in (30)). With c_1 and c_2 differing from the Levi-Civita connection, construction of the kinetic term may not be straightforward.

The analysis above ensures that additively transforming connections, such as the one (30), gives rise to a physically sensible mechanism where gravitational sector as well as the emergent scalar field from conformal transformation are both physical. Removal of the ghostly degree of freedom in metrical GR is a highly important aspect of the metric-affine gravity. Essentially, freeing connection from metric enables one to reach a physically consistent picture in regard to conformal frame changes in the gravitational action.

DISCUSSIONS AND CONCLUSION

In this work we have analyzed conformal transformations in metric-affine gravity (GR with affinity). The analysis is a comparative one between the GR with affinity and metricity. The main result of the analysis is that metric-affine gravity admits, under general additive transformations of the connection, conformally-related frames in which both gravitational and scalar sectors behave physically. The transformed frame consists of no ghost field, and exhibits emergent conformal invariance (sometimes called Weyl-Stückelberg invariance). The results can have far-reaching consequences for collider experiments [14, 30], cosmological evolution [7, 32, 33] as well as the electroweak breaking [13].

We have also analyzed equations of motion under general circumstances allowed by general covariance, and concluded that general Lagrangians allow for generalized conformal transformations of the connection without spoiling the essence of the theory in the transformed frame.

The affine gravitational action (15) can give rise to novel effects not found in the minimal version (the Einstein-Hilbert action). The conformally-reached frame can have various modifications in gravitational, matter as well as conformal factor (*i.e.* the Ω

related to $\bar{\phi}$ dynamics. The fact that the metric-affine gravity can accommodate correct gravitational dynamics plus non-ghost scalar degree of freedom under conformal transformations is an important aspect. This feature can have important implications in cosmological and other settings since transformation of system to a conformal frame now involves no ghostly degree of freedom. Indeed, the appearance of ghost fields, as mentioned in the text, is the major problem of conformal general relativity [34]. Therefore, the ghost-free dynamics established in the present work can have significant applications in conformal field theory, cosmology and gravitation.

ACKNOWLEDGEMENTS

The authors gratefully thank Barış Ateş for his mathematical contributions at the early stages of this work. Authors also thank to very conscientious referees for their comments and suggestions.

APPENDICES

A. Equations of motion

We have found that metric-affine gravity provides a means of generating non-ghost scalar field $\bar{\phi}$ by executing a more general transformation property as indicated in (30). However, we know that equations of motion relate $\Gamma_{\alpha\beta}^\lambda$ to Levi-Civita connection, and it is questionable if one can indeed realize such generalized transformation properties. For a detailed analysis of the problem, we will proceed systematically by examining different forms of geometrodynamical action densities.

- First of all, one notes that the affine gravitational action (15) becomes a highly conservative one for $\mathcal{L} = 0$. In this case, variation of action with respect to the connection $\Gamma_{\alpha\beta}^\lambda$ gives

$$\nabla_\lambda^\Gamma (\sqrt{-g} g^{\alpha\beta}) = 0 \quad (36)$$

where the covariant derivative of the tensor density is defined as

$$\nabla_\lambda^\Gamma \sqrt{-g} = \partial_\lambda \sqrt{-g} - \Gamma_{\alpha\lambda}^\alpha \sqrt{-g} \quad (37)$$

Then the equation (36) is solved uniquely for

$$\Gamma_{\alpha\beta}^\lambda = \check{\Gamma}_{\alpha\beta}^\lambda. \quad (38)$$

Therefore, the action (15) is equivalent to the action for metrical gravity in (10). The main advantage of metric-affine gravity (actually the Palatini formalism itself) is that one arrives at the equations of GR with no need to extrinsic curvature (which is needed in metrical gravity). In sum, with $\mathcal{L} = 0$, (15) gives an equivalent description of (10). We will elaborate more on this point below.

- There can, however, be various sources of departure from the action (15). These sources of departure are contained in \mathcal{L} . Let us first examine $\mathcal{L}_{\text{geo}}(g, \mathcal{D})$ which involves metric and the tensorial connection $\mathcal{D}_{\alpha\beta}^\lambda$. The tensorial connection $\mathcal{D}_{\alpha\beta}^\lambda$ gives rise to novel geometrodynamical structures not necessarily governed by the curvature tensor $\mathbb{R}_{\mu\beta\nu}^\alpha(\Gamma)$ and its contractions and higher powers (though such sources of $\mathcal{D}_{\alpha\beta}^\lambda$ are to be also included in $\mathcal{L}_{\text{geo}}(g, \mathcal{D})$). Indeed, the action can be added various new terms involving appropriate powers of $\mathcal{D}_{\alpha\beta}^\lambda$ as long as general covariance is respected. One notices that only even powers of $\mathcal{D}_{\alpha\beta}^\lambda$ can arise in the action [31]. Needless to say, presence of additional terms involving $\mathcal{D}_{\alpha\beta}^\lambda$ changes the equation of motion for $\Gamma_{\alpha\beta}^\lambda$. In particular, its dynamical equivalence to Levi-Civita connection, in the sense of (36), gets lost.

For explicating these points we go back to (15) and switch on $\mathcal{L}_{\text{geo}}(g, \mathcal{D})$ after which the $\mathcal{D}_{\alpha\beta}^\lambda$ dependence of the action takes the form

$$\begin{aligned} S_{EH}[g, \mathcal{D}] = & \int d^D x \sqrt{-g} \left\{ \frac{1}{2} M_\star^{D-2} g^{\mu\nu} \underbrace{[R_{\mu\nu}(\check{\Gamma}) + \mathcal{R}_{\mu\nu}(\mathcal{D})]}_{\mathbb{R}_{\mu\nu}(\Gamma)} \right. \\ & \left. - \Lambda_\star + \mathcal{L}_{\text{geo}}(g, \mathcal{D}) \right\} \end{aligned} \quad (39)$$

where we discarded $\mathcal{L}(g, \mathcal{D}, \psi)$ momentarily, to analyze the effects of geometrical part of \mathcal{L} in isolation. Actually, as we have mentioned before in (18), $\mathcal{L}_{\text{geo}}(\mathcal{D})$ can always be expressed in terms of torsion (which vanishes in our case), non-metricity, and curvature tensors. A more general discussion of the roles of non-metricity and torsion could be found in [36]. We here prefer to use generic function $\mathcal{L}_{\text{geo}}(\mathcal{D})$ instead of expressing it in terms of those tensor structures in (18). From (28) it follows that

$$\mathcal{R}_{\mu\nu}(\mathcal{D}) = \nabla_\alpha \mathcal{D}_{\mu\nu}^\alpha - \nabla_\nu \mathcal{D}_{\mu\alpha}^\alpha + \mathcal{D}_{\lambda\alpha}^\alpha \mathcal{D}_{\mu\nu}^\lambda - \mathcal{D}_{\lambda\nu}^\alpha \mathcal{D}_{\alpha\mu}^\lambda \quad (40)$$

in the action (39). Variation of the action with respect to $\mathcal{D}_{\alpha\beta}^\lambda(z)$ gives the equations of motion

$$\delta_\lambda^\beta g^{\mu\nu}(z) \mathcal{D}_{\mu\nu}^\alpha + g^{\alpha\beta}(z) \mathcal{D}_{\lambda\nu}^\nu(z) - g^{\mu\beta}(z) \mathcal{D}_{\lambda\mu}^\alpha(z) - g^{\beta\nu}(z) \mathcal{D}_{\lambda\nu}^\alpha(z) + \mathcal{G}_\lambda^{\alpha\beta}(g, \mathcal{D}) = 0 \quad (41)$$

where $\mathcal{G}_\lambda^{\alpha\beta}(g, \mathcal{D})$ stands for the variation of the geometrical part $\mathcal{L}_{\text{geo}}(g, \mathcal{D})$ with respect to $\mathcal{D}_{\alpha\beta}^\lambda(z)$.

- From (41) one immediately observes that, for $\mathcal{L}_{\text{geo}}(g, \mathcal{D}) = 0$ (in addition to assumed vanishing of the matter contribution), the tensorial connection identically vanishes, $\mathcal{D}_{\alpha\beta}^\lambda = 0$. This implies that the general connection $\Gamma_{\alpha\beta}^\lambda$ equals the Levi-Civita connection $\tilde{\Gamma}_{\alpha\beta}^\lambda$. In such a case, of course, $\Gamma_{\alpha\beta}^\lambda$ is expected to exhibit the same transformation properties as $\tilde{\Gamma}_{\alpha\beta}^\lambda$. Consequently, the general conformal transformation property (30) as well as the conclusions drawn from it will not hold for minimal Lagrangians, like (15) with $\mathcal{L} = 0$. In this sense, analysis of the previous section, though designed to show how varying conformal transformation properties of $\Gamma_{\alpha\beta}^\lambda$ modify the ghostly nature of $\bar{\phi}$, is physically sensible yet incomplete for it does not take into account the effects of non-vanishing \mathcal{L} effects.
- We have just concluded that we need non-vanishing \mathcal{L} for maintaining the independence of $\Gamma_{\alpha\beta}^\lambda$ from $\tilde{\Gamma}_{\alpha\beta}^\lambda$. Now it proves useful to check some reasonable forms of $\mathcal{L}_{\text{geo}}(g, \mathcal{D})$ in light of the equations of motion (41). Leaving aside the single-derivative terms as well as quadratic ones whose special forms are already contained in the curvature tensor, the lowest-order terms which can contribute to geometrical part take the form

$$\begin{aligned} \mathcal{L}_{\text{geo}}(g, \mathcal{D}) = & A_{\lambda\rho\zeta\epsilon}^{\alpha\beta\mu\nu\chi\xi\eta\kappa}(g) \mathcal{D}_{\alpha\beta}^\lambda \mathcal{D}_{\mu\nu}^\rho \mathcal{D}_{\chi\xi}^\zeta \mathcal{D}_{\eta\kappa}^\epsilon(\mathcal{D}) \\ & + B_{\lambda\zeta}^{\alpha\beta\mu\nu\rho\theta}(g) \nabla_\mu \mathcal{D}_{\alpha\beta}^\lambda \nabla_\nu \mathcal{D}_{\rho\theta}^\zeta + \dots \end{aligned} \quad (42)$$

where A and B are tensorial structures composed of the metric tensor. They are supposed to contain all possible combinatorics of the indices. It is clear that, after computing $\mathcal{G}_\lambda^{\alpha\beta}(g, \mathcal{D})$ from this combination, the equations of motion (41) will yield non-vanishing $\mathcal{D}_{\alpha\beta}^\lambda$ even without including its derivatives. Indeed, having (42) at hand, the equations of motion (41) take the form

$$\begin{aligned} & \mathcal{D}_{\rho\theta}^\sigma \left[g^{\rho\theta} \delta_\lambda^\beta \delta_\sigma^\alpha + g^{\alpha\beta} \delta_\sigma^\theta \delta_\lambda^\rho - g^{\theta\beta} \delta_\sigma^\alpha \delta_\lambda^\rho - g^{\beta\theta} \delta_\sigma^\alpha \delta_\lambda^\rho \right. \\ & + \mathcal{D}_{\chi\xi}^\zeta \mathcal{D}_{\eta\kappa}^\epsilon \left(A_{\lambda\sigma\zeta\epsilon}^{\alpha\beta\rho\theta\chi\xi\eta\kappa} + A_{\lambda\sigma\zeta\epsilon}^{\rho\theta\alpha\beta\chi\xi\eta\kappa} \right) \\ & + \mathcal{D}_{\mu\nu}^\zeta \mathcal{D}_{\chi\xi}^\epsilon \left(A_{\sigma\zeta\lambda\epsilon}^{\rho\theta\mu\nu\alpha\beta\chi\xi} + A_{\sigma\zeta\lambda\epsilon}^{\rho\theta\mu\nu\chi\xi\alpha\beta} \right) \Big] \\ & - \nabla_\rho \nabla_\theta \mathcal{D}_{\mu\nu}^\sigma \left(B_{\lambda\sigma}^{\rho\theta\alpha\beta\mu\nu} + B_{\lambda\sigma}^{\rho\theta\mu\nu\alpha\beta} \right) = 0. \end{aligned} \quad (43)$$

These equations automatically suggest that $\mathcal{D}_{\alpha\beta}^\lambda \neq 0$ (or $\Gamma_{\alpha\beta}^\lambda \neq \tilde{\Gamma}_{\alpha\beta}^\lambda$) even if $\mathcal{L}_{\text{geo}}(g, \mathcal{D})$ does not include its derivatives (the coefficients B vanish). If derivative terms vanish, then $\mathcal{D}_{\alpha\beta}^\lambda$ is obtained in terms of the metric tensor with, however, a general structure which should resemble (30) in any case. The details of the structure depend on how the coefficients $A_{\lambda\rho\zeta\epsilon}^{\alpha\beta\mu\nu\chi\xi\eta\kappa}$ are organized in terms of the metric tensor.

On the other hand, if the derivative terms are included then $\mathcal{D}_{\alpha\beta}^\lambda$ becomes a dynamical field. In this case, again, one obtains a non-trivial $\Gamma_{\alpha\beta}^\lambda$ not equaling $\tilde{\Gamma}_{\alpha\beta}^\lambda$.

A simple illustrative example for the aforementioned Lagrangian would be the geometrical quantity

$$\mathcal{L}_{\text{geo}}(g, \mathcal{D}) = a \mathbb{C}_{\alpha}^{\mu\beta\nu} \mathbb{C}_{\mu\beta\nu}^\alpha \quad (44)$$

where a is a suitable constant of mass dimension $D - 4$, and $\mathbb{C}_{\mu\beta\nu}^\alpha(\Gamma)$ is the D -dimensional Weyl curvature tensor [28]. It is nothing but the traceless part of the Riemann curvature tensor $\mathbb{R}_{\alpha\nu\beta}^\mu(\Gamma)$, and has the same index symmetries. The resulting field equations will be of the form (43) which tells us that the tensorial connection $\mathcal{D}_{\mu\nu}^\lambda$ is an independent dynamical field. (Discussions of these points can be found in [35] for the case with non-vanishing torsion.)

From this analysis we conclude that, the analysis of the previous section, which has clearly shown how $\bar{\phi}$ becomes a non-ghost scalar for a general $\Gamma_{\alpha\beta}^\lambda$ transforming as in (30), in general, the connection $\Gamma_{\alpha\beta}^\lambda$ does not reduce to $\tilde{\Gamma}_{\alpha\beta}^\lambda$, and a conformal transformation property as in (30) can result in a multitude of ways.

- Another source of departure from (15) is the matter Lagrangian $\mathcal{L}(g, \mathcal{D}, \psi)$. By switching on this Lagrangian one can still find additional structures which cause $\Gamma_{\alpha\beta}^\lambda$ to be independent of $\tilde{\Gamma}_{\alpha\beta}^\lambda$. Then the main difference from the previous analysis will be the dependence of the $\Gamma_{\alpha\beta}^\lambda$ on the matter fields themselves – a situation not discussed before. The question of how $\mathcal{L}(g, \mathcal{D}, \psi)$ involves $\Gamma_{\alpha\beta}^\lambda$ is easy to answer given that, rather generically, connection-dependent terms arise in scalar and spinor field theories already at the renormalizable level [6]. In such cases it could be difficult to arrange general conformal transformations of the form (30) yet one should keep such matter sector sources in mind in analyzing the conformal transformation properties in non-Riemannian geometries.

B. Ricci Scalar Under Multiplicatively Transforming Connection

In this appendix, we sketch the calculations showing that the multiplicatively transformed Ricci “scalar” $\tilde{g}^{\mu\nu}\tilde{\mathbb{R}}(\Gamma)_{\mu\nu}$ is a true scalar under general coordinate transformations. Indeed, by direct calculation, one finds step by step the following relations:

$$\begin{aligned}
& \Omega^{-2}\partial_\alpha f(\Omega) (g^{\mu\nu}\Gamma_{\mu\nu}^\alpha - g^{\mu\alpha}\Gamma_{\mu\lambda}^\lambda) \\
& + \Omega^{-2} [f^2(\Omega) - f(\Omega)] (\Gamma_{\alpha\lambda}^\alpha g^{\mu\nu}\Gamma_{\mu\nu}^\lambda - \Gamma_{\nu\lambda}^\alpha g^{\mu\nu}\Gamma_{\mu\alpha}^\lambda) \\
\Rightarrow & \Omega^{-2}\partial_\alpha f(\Omega) \left[\frac{\partial x^\mu}{\partial x^{\mu'}} \frac{\partial x^\nu}{\partial x^{\nu'}} g^{\mu'\nu'} \left(\frac{\partial x^\alpha}{\partial x^{\alpha'}} \frac{\partial x^{\mu'}}{\partial x^\mu} \frac{\partial x^{\nu'}}{\partial x^\nu} \Gamma_{\mu'\nu'}^{\alpha'} + \frac{\partial x^\alpha}{\partial x^{\alpha'}} \frac{\partial^2 x^{\alpha'}}{\partial x^\mu \partial x^\nu} \right) \right. \\
